Lecture 5: Inheritance, Interfaces, and Polymorphism

Life is structures in Layers

Wholeness of the Lesson

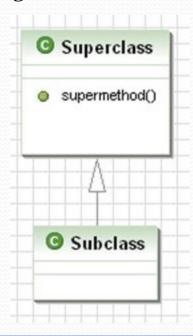

Java supports inheritance between classes in support of the OO concepts of inherited types and polymorphism. Interfaces support encapsulation, play a role similar to abstract classes, and provide a safe alternative to multiple inheritance. Likewise, relationships of any kind that are grounded on the deeper values at the source of the individuals involved result in fuller creativity of expression with fewer mistakes.

Outline of Topics

- Introduction to Inheritance Example of Subclassing a Class
- The "IS-A" and LSP Criteria for Proper Use of Inheritance
- Access Modifier protected
- Rules for Subclass Constructors
- Inheritance and the Object Class
- Introduction to Polymorphism
- Order of Execution with Inheritance
- Abstract Class
- Introduction to Java Interfaces, Comparable, Functional Interfaces
- New Java 8 Features for Interfaces
- Introduction to the Reflection Library
- The Object Class
 - The toString Method
 - The equals Method
 - The hashCode Method
 - The clone Method: Shallow and Deep Copies

Introduction to Inheritance

• Definition. A class Subclass inherits from another class Superclass if objects of type Subclass have automatic access to the "available" methods and variables that have been defined in class Superclass. By "automatic access" we mean that no explicit instantiation of (or reference to) the class Superclass is necessary in order for objects of type Subclass to be able to call methods defined in class Superclass. By "available" methods and variables, we mean methods and variables that have been declared either public or protected (or have package level access if in the same package).

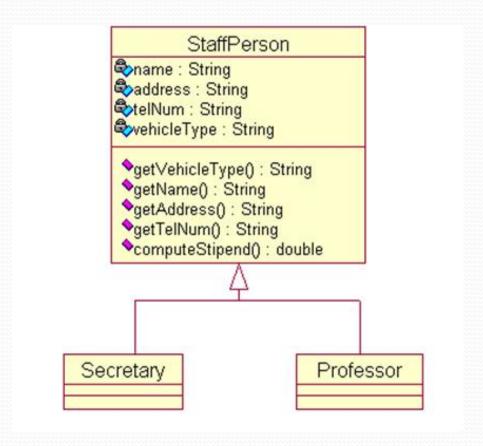

```
class Superclass {
   protected void supermethod() {
        int x = 0;
   }
}
class Subclass extends Superclass {
}
class Main {
   public static void main(String[] args)
   {
        Subclass sub = new Subclass();
        sub.supermethod();
   }
}
```

A class, method, variable labeled *protected* is accessible to all *subclasses*.

 Motivation. In our programming projects, we may find that we define two classes that have many of the same fields and methods. It is natural to think of a single class that generalizes the two classes and that contains the code needed by both.

```
Professor
Secretary
 properties:
                                  properties:
      name
                                        name
                                       address
      address
      phone number
                                        phone number
      drivesVehicle
                                        drivesVehicle
      salary
                                        salary
 behavior:
                                   behavior:
      computeSalary()
                                        computeSalary()
```

<u>Strategy</u>: Create a generalization of Secretary and Professor from which both of these classes inherit. A StaffPerson class can be defined having all four fields and related methods, and Secretary and Professor can be defined so they are subclasses of StaffPerson.

When the classes have this relationship, we may view the type of an instance of a subclass as being that of the superclass. For example, we can instantiate like this:

```
StaffPerson person1 = new Professor():
StaffPerson person2 = new Secretary();
```

This is similar in spirit to the automatic conversions that are done for primitive types:

```
byte b = 8;
int k = b;
```

An Example of Superclass and Subclass: Manager subclass of Employee

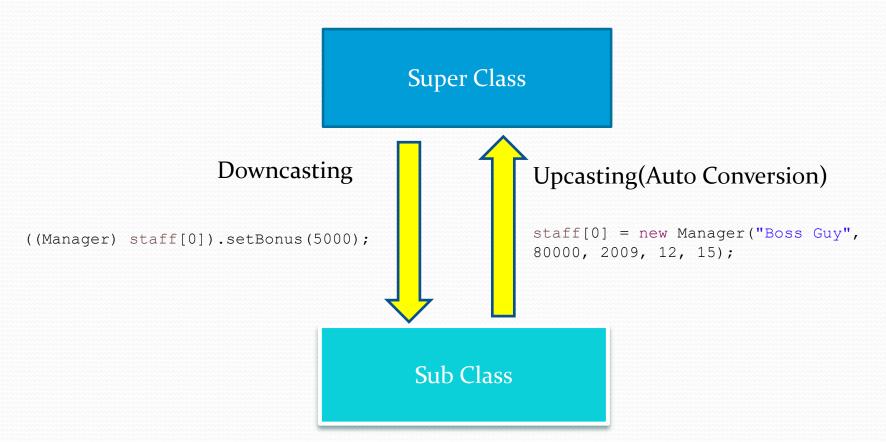

```
class Employee {
     //instance fields
     private String name;
     private double salary;
     private LocalDate hireDay;
     Employee (String aName, double aSalary, int aYear, int aMonth, int aDay) {
          name = aName;
          salary = aSalary;
          hireDay = LocalDate.of(aYear,aMonth,aDay);
     // instance methods
     public String getName() {
          return name;
     public double getSalary() {
          return salary;
     public LocalDate getHireDay() {
          return hireDay;
     public void raiseSalary(double byPercent) {
          double raise = salary * byPercent / 100;
          salary += raise;
```

```
class Manager extends Employee {
         private double bonus;
         public Manager(String name, double salary, int year, int month, int day) {
                    super(name, salary, year, month, day);
                   bonus = 0;
          @Override
         public double getSalary() {
                   // no direct access to private variables of
                   // superclass
                    double baseSalary = super.getSalary();
                    return baseSalary + bonus;
         public void setBonus(double b) {
                   bonus = b;
```

```
public class MainEmployee {
    // Inheritance Example
    public static void main(String[] args) {
        Employee[] staff = new Employee[3];
        staff[0] = new Manager("Boss Guy", 80000, 2009, 12, 15);
        ((Manager) staff[0]).setBonus(5000); //Downcasting
        staff[1] = new Employee("Jimbo", 50000, 2012, 10, 1);
        staff[2] = new Employee("Tommy", 40000, 2013, 3, 15);
        // print names and salaries
        for (Employee e : staff) {
            System.out.println("Name: " + e.getName() + "\nSalary: " +
                  e.getSalary() + "\nHire Day :" + e.getHireDay() + "\n");
```

Demo code : lesosn5.empmanager

Typecasting

Points to observe:

- Manager provides all the "services" of Employee, with additional functionality (involving bonuses) and overriding functionality (getSalary method) - so it's a good candidate for extending Employee.
- Every java class inherit Object class implicitly, Object methods.
- We use the *extends* keyword to indicate that Manager is a *subclass* of Employee, a Manager IS an Employee, but not vice versa
- A Manager instance can freely use the getName and getHireDay methods of its superclass Employee no need to re-code these methods. However, special methods that are unique to Manager (in particular, the setBonus method) cannot be called on an Employee instance, but with typecasting you can.

```
Manager m = new Manager(. . .);
m.getName();
                             //ok
m.setBonus(5000); //ok
Employee e = new Employee(. . .);
                             //ok
e.getName();
e.setBonus(5000); //compiler error, as an Employee IS not a Manager!
((Manager)e).setBonus(3000); //runtime error, Employee cannot cast to Manager!
Employee m = new Manager(. . .);
                                      //ok, a Manager IS an Employee!
                               //ok
m.qetName();
((Manager)m).setBonus(5000);
                               //ok
                                      Downcasting
```

- We override the getSalary method in the Manager class.
 - This means that the method is defined differently from its original version in Employee. A Manager object computes salary differently from Employee objects.
- Still wish to use getSalary in Employee, but add the value of bonus to it. How can this be done?
 - In general, how to access the *superclass version* of a method from within a *subclass*?

Solution: Use **super** to indicate that you are accessing the superclass version.

Best Practice. Use the @Override annotation on getSalary. Two reasons:

- It is possible for another user of your code not to realize that your method overrides a method in a superclass.
- Provides a compiler check that your method really is overriding a superclass method.

• In the Manager constructor, we wish to reuse the constructor that is found in Employee, but we also want to include more code. This is accomplished by using the super keyword again (but it has a different meaning here).

Like **this** in constructor, the use of **super** must occur on the first line of the constructor body.

- **Polymorphic types**. The 0th element of the staff array was defined to be of type Manager, yet we placed it in an array of Employee objects. An important example of polymorphism is how a parent class refers to a child class object. In fact, any object that satisfies more than one IS-A relationship is polymorphic in nature. Every object in Java passes a minimum of two IS-A tests: one for itself and one for Object class.
- Dynamic binding. When the <code>getSalary</code> method is called on <code>staff[0]</code>, the version of <code>getSalary</code> that is used is the version that is found in the <code>Manager</code> class. This is possible because the JVM keeps track of the actual type of the object when it was created (that type is set with execution of the "new" operator). The correct method body (the version that is in Manager) is associated with the <code>getSalary</code> method at runtime this "binding" of method body to method name is called <code>late binding</code> or <code>dynamic binding</code>.

Polymorphism

- Polymorphism refers to the ability of an object to take on many forms.
- A variable of a supertype can refer to a subtype object.
- Compile time/Static Polymorphism(Early/static Binding) :
 - Method overloading

```
public int add(int x, int y) { //method 1 }
public int add(int x, int y, int z) { //method 2 }
public int add(double x, int y) { //method 3 }
public int add(int x, double y) { //method 4 }
E.g.
this.add(9, 9.99); // Method 4 will be called
```

- Runtime/Dynamic Polymorphism(Late/dynamic binding):
 - Method Overriding

```
[superclass] obj = new [subclass]
E.g.
Employee e = new Manager(...);
e.getSalary(); // Overridden getSalary() will be called.
```

Rules for overriding

- 1. The method must be apply to an instance method. Overriding does not apply to static method.
- 2. The overriding method must have the same name as the overridden method.
- 3. The overriding method must have the same number of parameters of the same type in the same order as the overridden method
- 4. Return type of the overriding and overridden methods must be the same correct? See next slide.
- 5. The access level of the overriding method must be at least the same or more relaxed than that of the overridden method.

Overridden(Parent) Overriding Access level (Child)

public public

protected public, protected

package-level public, protected, package-level

Is it overriding?

```
class A{}
class B extends A {}
class Parent{
  A fun(){
    System.out.println("Parent
fun()");
    return new A();
class Child extends Parent{
  B fun(){
    System.out.println("Child fun()");
    return new B();
```

Overloading vs. Overriding

- Overridden methods are in different classes related by inheritance; overloaded methods can be in the same class.
- Overridden methods have the same signature and compatible return type; overloaded methods have the same name but a completely different parameter list, return types do not play any roles in overloading.
- Overriding applies only to instance methods; Any method(static/non-static) can be overloaded.
- Overloading is determined during the compile time but overriding determined during the runtime.

Inheritance and Access

Base class access

Accessibility in derived class

public

Yes

protected

Yes

private

Inaccessible

Unspecified (package access-default)

Yes

Access Modifier

- Visibility modifiers determine which class members are inherited and which are not
- Variables and methods declared with public visibility are inherited; those with private visibility are not
- But public variables violate the principle of encapsulation
- There is a third visibility modifier that helps in inheritance situations: protected

The protected Modifier

- The protected modifier allows a member of a base class to be inherited into a child
- Protected visibility provides more encapsulation than public visibility does
- However, protected visibility is not as tightly encapsulated as private visibility
- Try the implementation of next slide to understand modifiers.

```
package p1;
  public class C1 {
                                public class C2 {
     public int x;
                                  C1 o = new C1();
     protected int y;
                                  can access o.x;
     int z:
                                  can access o.y;
     private int u;
                                  can access o.z;
                                  cannot access o.u:
     protected void m() {
                                  can invoke o.m();
                                  package p2;
  public class C3
                                     public class C4
                                                                  public class C5 {
            extends C1 {
                                              extends C1 {
                                                                    C1 o = new C1():
     can access x:
                                       can access x:
                                                                    can access o.x:
                                       can access y;
                                                                    cannot access o.y;
     can access y;
                                       cannot access z:
                                                                    cannot access o.z:
     can access z:
     cannot access u:
                                       cannot access u;
                                                                    cannot access o.u;
     can invoke m();
                                                                    cannot invoke o.m():
                                       can invoke m();
```

Visibility modifiers are used to control how data and methods are accessed.

Main Point

One class (the *subclass*) inherits from another class (the *superclass*) if all proteced and public data and methods in the superclass are automatically accessible to the subclass, even though the subclass may have additional methods and data not found in the superclass. Java supports this notion of inheritance. In Java syntax, a class is declared to be a subclass of another by using the extends keyword. Likewise, individual intelligence "inherits from" cosmic intelligence, though each "implementation" is unique.

Correct Use of Inheritance

Here are two tests to check whether one class should inherit from another.

- Manager IS-A Employee it's not just that the two classes have some methods in common, but a manager really is an employee. This helps to verify that inheritance is the right relationship between these classes.
- Liskov Substitution Principle (LSP). Another test is: Can a Manager instance be used whenever an Employee instance is expected? The answer is yes, since every manager really is an employee, and partakes of all the properties and behavior of an employee, though managers support extra behavior.

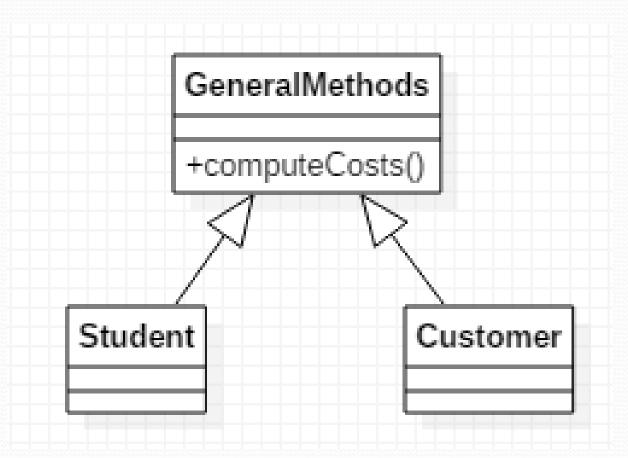

Common Mistake: Indiscriminate Generalization

• The following strategy is a <u>mistake</u>: Place methods common to several classes into one superclass for all of them. Then all the classes have immediate access to methods that they all can use.

This is undesirable because, eventually, some methods and variables in the superclass will not be relevant for some of the subclasses – those subclasses will therefore offer "services" that they cannot possibly provide.

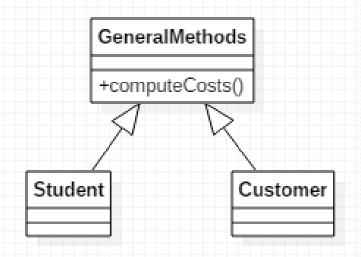

(continued)

• At first, this may seem reasonable

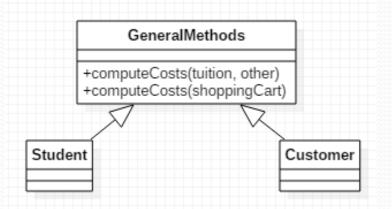

(continued)

At first, this may seem reasonable

 As your project evolves, you may find that different versions of computeCosts are needed for Student and Customer

Now a Customer seems to be supporting computeCosts with input tuition and other. This undermines the purpose of the Customer class

(continued)

• Often, common methods can be placed in a *utility class*.

```
public class Student {
    void aMethod() {
        double tuition = 5000;
        double other = 3000;
        //...
        double val = Util.computeCosts(tuition, other);
        //...
}

public class Customer {
    void aMethod() {
        ShoppingCart cart = new ShoppingCart();
        //...populate cart
        double val = Util.computeCosts(cart);
        //...
}
```

```
public class Util {
    private Util() {
        //private constructor
    }
    public static double computeCosts(double tuition, double other) {
        double cost = 0.0;
        //. . .compute
        return cost;
    }
    public static double computeCosts(ShoppingCart cart) {
        double cost = 0.0;
        //unpack cart and compute
        return cost;
    }
}
```

Main Point

As a matter of good design, a class C should not be made a subclass of a class D unless C "IS-A" D. Likewise, individual intelligence "is" cosmic intelligence, though this relationship requires time to be recognized as true.

Rules for Subclass Constructors

The Rule:

a subclass constructor <u>must</u> make use of one of the constructors from its superclass

<u>Reason for the rule</u> The state of the superclass (values of its instance variables) should be set *by the superclass* (not by the subclass). so during construction, the subclass must request the superclass to first set its state, and then the subclass may perform further initialization of its own state.

Example. Employee/Manager:

Note: It is not necessary for any of the subclass constructors to have the same signature as any of the superclass constructors. However, each of the subclass constructors must access one of the superclass constructors in its implementation.

The subclass may make use of the implicit default constructor *only if* either

- A. the no-argument constructor of the superclass has been explicitly defined, OR
- B. no constructor in the superclass is explicitly defined In either of these cases, the subclass may make use (possibly implicitly) of the superclass's default constructor.

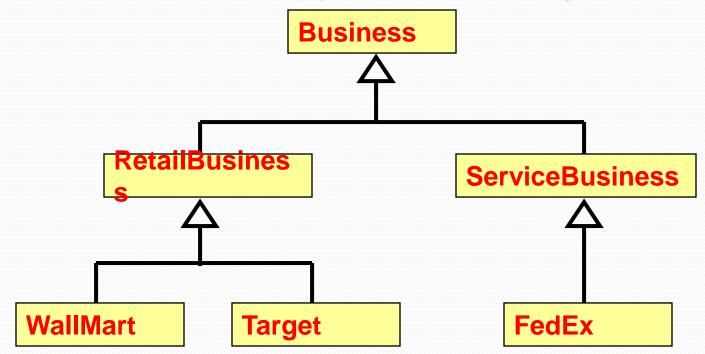

```
//Case A.
class Employee{
       Employee(String name, double salary, int y, int m, int d) {
               //...//
       //explicit coding of default constructor since another
       //constructor is present
       Employee() {
               //...//
class Manager extends Employee {
       //no explicit constructor call here, so the superclass
       //default constructor is used implicitly
```

```
//Case B.

class Employee{
    //...//
}
class Manager extends Employee {
    //...//
}
```

Class Hierarchies

 A child class of one parent can be the parent of another child, forming a *class hierarchy*.

Multiple Inheritance

- Multiple inheritance allows a class to be derived from two or more classes, inheriting the members of all parents
- Collisions, such as the same variable name in two parents, have to be resolved
- Java does not support multiple inheritance, only supports single inheritance, meaning that a derived class can have only one parent class
- In most cases, the use of interfaces gives us aspects of multiple inheritance without the overhead

Inheritance and the Object Class

• In Java, there is a class called Object. Every class created in Java (either in the Java libraries, or user-defined) belongs to the inheritance hierarchy of Object.

For example:

```
class MyClass {
}
```

This MyClass class automatically inherits from Object, even though we do not write syntax that declares this fact.

In later slides, we will discuss the (primarily public) methods that belong to Object, and that are therefore inherited by every class in Java.

Using the instanceof operator to check type.

The following code returns true:

```
"Hello" instanceof java.lang.String
```

In general, you can query Java about the type of any runtime object by using instanceof. The general synatx is

```
ob instanceof <classname>
```

where ob is of type Object (or any subtype). This expression will return true if the runtime type of ob really is of the specified type, or if the class of ob is a subclass of (or a subclass of a subclass of...etc) the specified type. Therefore, for example, if e is an instance of Employee and s is a String, both of the following are true

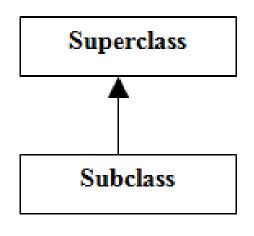

```
e instanceof Object
s instanceof Object
```

Whenever the instanceof operator returns true, the object on the left side of the expression can be viewed as having type indicated on the right side (via polymorphic type assignment). So in this example, we could type e and s above as Objects:

instaceof and casting

```
Object[] stuff = { "Java", 10.11, 12, 13, 16.11, 20, "Hi" };
double sum = 0;
for (int i = 0; i < stuff.length; i++) {
   if (stuff[i] instanceof Number) { // checking instance
        Number next = (Number) stuff[i]; // Down casting
        sum += next.doubleValue();
   }
}
System.out.println("Sum of Doubles = " + sum);</pre>
```

Order of Execution with Inheritance

Suppose, as in a typical case, we have Subclass as a subclass of Superclass. When we run

new Subclass()

the sections of the code are executed according to the following scheme:

- In Superclass, all static variables are initialized and all static initialization blocks are run, in the order in which they appear in the file.
- In Subclass, all static variables are initialized and static initialization blocks are run, in the order in which they appear in the file.
- In Superclass, all instance variables are initialized and all object initialization blocks are run, in the order in which they appear in the file
- In Superclass, the (relevant) constructor is run.
- In Subclass, all instance variables are initialized and all object initialization blocks are run, in the order in which they appear in the file
- In Subclass, the (relevant) constructor is run.

[See Demo - ClassE.java]
